

Dynamic workflows — prompts to try

A workflow is a JavaScript harness that Claude writes for your task. It starts many agents, each with a clean context. Ask for one in your own words, or write **ultracode**.

classify-and-act · fan-out-and-synthesize · adversarial verification · generate-and-filter · tournament · loop-until-done

YOUR PAPER

- “Use a workflow to check each citation in my draft. Read each cited paper. Flag each claim that its source does not support.”
- “Run a workflow with four reviewers: methodology, missing baselines, statistics, novelty. Rank the criticisms. Give me a fix list.”
- “Trace each number in my abstract to a table and to the eval script. Flag each number that you cannot trace.”
- “Go through my draft and verify every technical claim against the codebase with a workflow. I do not want to ship anything wrong.”

YOUR CODE

- “Use a workflow to hunt for silent bugs in my training code: data leakage, eval contamination, masking errors, seed problems. Keep only the bugs that get a failing ten-line test.”
- “Use a workflow to check each equation in the paper against the function that implements it.”
- “This test fails maybe 1 in 50 runs. Set up a workflow to reproduce it. Form competing theories about the race. Do not stop until one theory survives the evidence.”
- “Use a workflow to rename `Encoder` to `Backbone` everywhere, one worktree per module, with an adversarial review before merge.”

YOUR EXPERIMENTS

- “Run a workflow that tunes my proxy run until val loss is below 2.10 or a 500k token budget is gone. Change one thing per wave. Build an HTML report at the end.”
- “Why did run 41 diverge? Spawn agents that make hypotheses from the logs, the config, and the data — separately. Then let refuters attack each hypothesis.”
- “Use a workflow to read this finished sweep and build a one-page HTML explainer: curves, ablations, failure cases.”

THE LITERATURE

- “Use a workflow to sweep for related work: by keyword, by author, by citation graph, by venue. Stop when two waves find nothing new.”
- “Take these 12 papers. Extract the core claims. Show me where the papers disagree, and whether their setups differ.”

- “Before I adopt this benchmark, use a workflow to check for contamination reports, label errors, and saturation.”

JUDGING WITH A RUBRIC

- “Here is my rubric. Score my chapter with one judge per criterion. Each score must cite evidence from the text.”
- “Have two agents mark each submission blind against the rubric. Escalate only the criteria where they disagree.”
- “Sort these 200 error cases by severity with a tournament of pairwise judges.”
- “Interview me with `AskUserQuestion` to build a rubric first. Then rank these 80 outputs against it and double-check the top ten.”

TASTE AND EXPLORATION

- “I need a name for this method. Use a workflow to brainstorm many options and run a tournament to pick the top 3.”
- “Tear my research statement apart from an advisor’s, a Reviewer-2’s, and a grant panel’s perspective.”
- “Quick workflow: adversarially check the assumption I just made.”

BUILD YOUR OWN TOOLS

- “Create a single HTML tool where I can manually make diagrams like this. Seed it with one of the workflows. Let me move the nodes, edit the text, and add more nodes.”
- “Create a global skill that makes diagrams in this exact style, so any future session can draw one.”

GOOD TO KNOW

- Set a limit in the prompt: “use a 200k token budget.” The limit is hard.
- Workflows run in the background. Type `/workflows` to watch.
- If the run stops, resume the session. Completed agents are not run again.
- Press `s` in the workflow menu to save a workflow. Share it as a skill.
- Pair with `/loop` for repeated tasks and `/goal` for a hard finish line.
- Most tasks do not need a workflow. Ask: does this task really need more compute?

Why this works: one context window must plan and do the work. Long tasks cause laziness, self-preference, and goal drift. A workflow gives each agent one small goal and a clean context.
